## **Tandy Service Manual**

### Navigating this CD

To view the contents of this CD use the bookmarks and Adobe Reader's forward and back buttons to browse through the pages. Alternatively use any table of contents or book index to look for specific information and then use Adobe Reader's page navigation controls in the status bar at the bottom of the window to go to the relevant page.

### Searching this CD

- This CD is searchable using Adobe Acrobat Reader 4 or later. It is also *FASTFIND* enabled, giving very fast searches of all files on the CD at once! The *FASTFIND* search enhancement only works with Adobe Reader 6 or later. Use the Binoculars/Search icon in Adobe Reader or "Search" under the Edit menu to initiate all searches.
- For more information on advanced searching and other tips for the best search results click here
- Generally 95% 99% of the words can be searched. Where the original type was poor the words may not be recognised for searching.

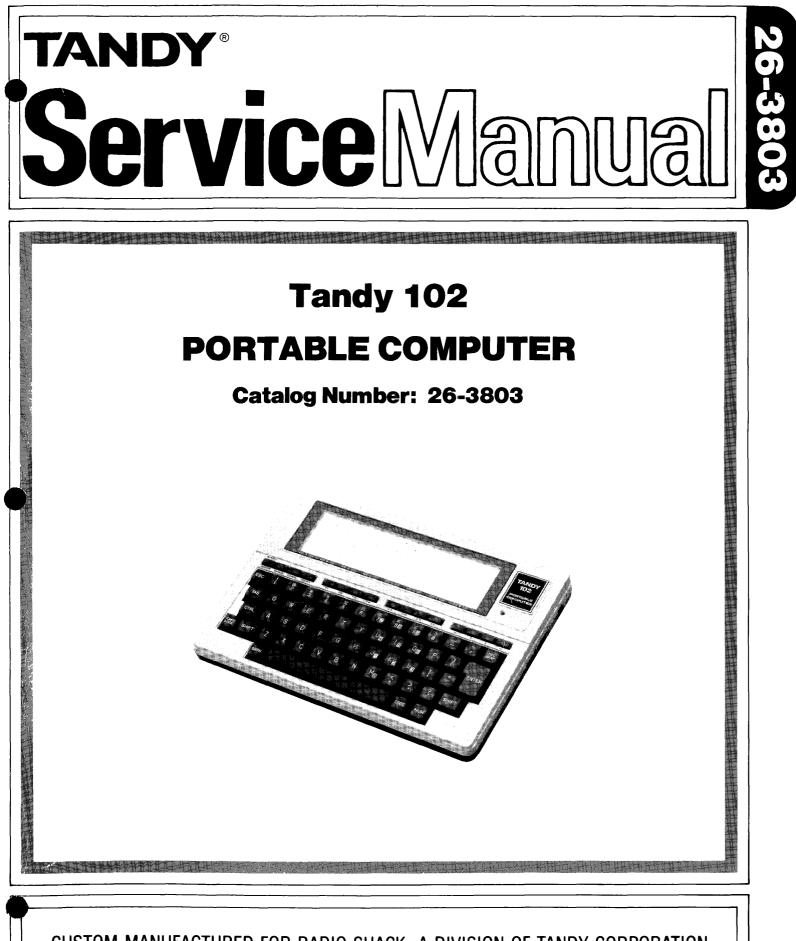

## The technical advancements that allow this searching bring a wonderful finding aid but there is still no substitute for reading the book!

Copyright ©2006 Archive CD Books Australia Pty Ltd. All Rights Reserved

For more books on CD from Archive CD Books Australia, see the web site at www.archivecdbooks.com.au

Archive CD Books Australia exists to make reproductions of old books, documents and maps available on CD, and to co-operate with family and local history societies, libraries, museums and record offices to digitise their collections in return for other benefits.

# I. INTRODUCTION

This manual is prepared for the Tandy 102 technicians working in field or in repair centers. Users of this manual should be acquainted with the 80C85A microprocessor, the 81C55 PIO and the 6402 UART. If you need more detailed information, refer to Appendix C in this manual.

This manual consists of seven sections and three appendices:

### Section I

This section provides general information on the Tandy 102 such as specifications, external views and internal views.

#### Section II

This section describes the disassembly procedures.

### Section III

This section describes the maintenance of the Tandy 102.

### **Section IV**

This section describes the general theory of operation for the Tandy 102.

### Section V

This section describes how to troubleshoot the Tandy 102.

### **Section VI**

This section provides an exploded view and parts list of the Tandy 102.

### **Section VII**

This section provides the schematics, PCB diagrams, and silkscreen views of the PCBs of the Tandy 102.

### **Appendix A**

This appendix provides instructions for installing the optional ROM and additional RAMs.

### **Appendix B**

This appendix provides the character code table, keyboard layouts and connector pin assignments.

### Appendix C

This appendix provides the technical information of the 80C85A, 81C55, 6402 and LCD.

## System Overview

Tandy 102 portable computer is a low cost version of the Radio Shack TRS-80 Model 100 Portable Computer. The Tandy 102 is fully compatible with the Model 100 in its software so that both system users can take advantage of the large number of programs available.

The Tandy 102 has the following applications programs in the standard ROM: BASIC, TEXT, TELCOM, ADDRSS, SCHEDL and TELCOM.

## **External View**

- 1 **Keyboard:** Can be used like the standard typewriter. However, the Tandy 102 does have a few special keys. (See Appendix B of this manual for more details.)
- 2 LCD Screen: The Tandy 102 display has eight lines that allow 40 characters on each line.
- **3 Power Switch:** Move this switch towards the front to turn the power on. To conserve the batteries, the Tandy 102 automatically turns the power off if you do not use it for 10 minutes in default setting.
- 4 Low Battery Indicator: Before the Tandy 102 is operational batteries become exhausted, this indicator will illuminate.
- **5 Display Adjustment Dial:** This control adjusts the contrast of the LCD display relative to the viewing angle.
- 6 External Power Adapter Connector: Connect the appropriate and of Radio Shack's AC Power Supply (Catalog Number 26-3804, optional/extra) to this connector. Connect the other end of the power supply to a standard AC wall-outlet or approved power strip.

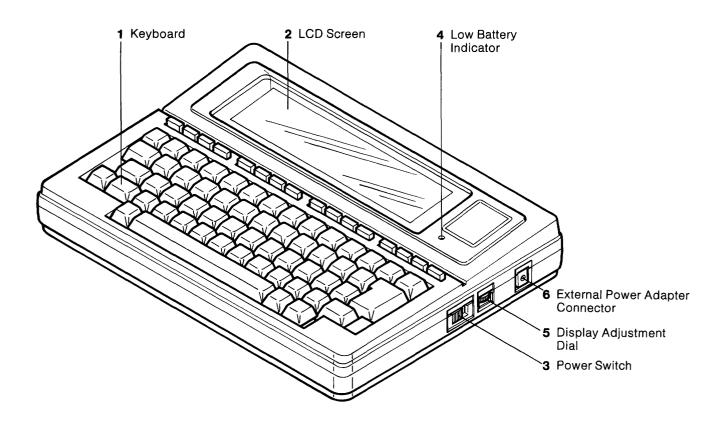

Figure 1-1. Front View

- 1 **RESET Switch:** If the Tandy 102 "locks up" (i.e., the display "freezes" and all keys seem to be inoperative), press this button to return to the Main Menu (start-up). It is not likely that the Tandy 102 will lock-up when you are using the built-in applications programs, however, it may occur with customized programs.
- 2 **RS-232C Connector:** Attach a DB-25 cable (such as Radio Shack Catalog Number *26-1408*) to this connector when you need to receive or transmit serial information. When you communicating directly with another TRS-80 computer, a Null MODEM Adapter (*26-1496*) is required. An 8" Cable Extender (*26-1497*) may also be required.
- **3** SYSTEM BUS Connector: Connect this connector to the TRS-80 Disk/Video interface (*26-3806*), using the system bus cable.
- **4 PRINTER Connctor:** For hard-copy printouts of information, attach any Radio Shack parallel printer to this connector, using an optional/extra printer cable.
- 5 Direct-Connect MODEM (PHONE) Connector: When communicating with another computer via the Tandy 102's built-in MODEM, connect the round end of the optional/extra MODEM cable to this connector.
- 6 **CASSETTE Recorder Connector:** To save or load information, on a cassette tape, connect the cassette recorder here. An optional/extra cassette recorder (and cable) is required.
- 7 Bar Code Wand Connector: Attach the optional/extra bar code wand to this connector. Note that special bar code reader software is required.
- 8 **DIR/ACP Selector:** This selector allows you to select either a direct or acoustic coupler connection. If you are communicating with another computer over the phone lines via the built-in, direct-connect MODEM, set this switch to the DIR position. If you are using the optional/extra Model 100 Acoustic Coupler (*26-3805*), set this connector to the ACP position.
- **9 ANS/ORIG Selector:** If you are "originating" a phone call to another computer, set this switch to ORIG. If another computer is calling your Tandy 102, set to ANS.

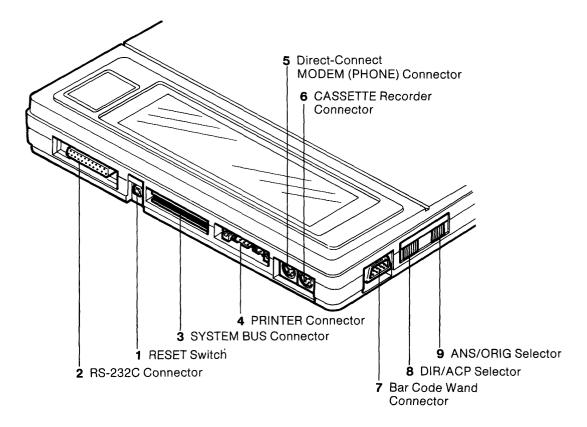

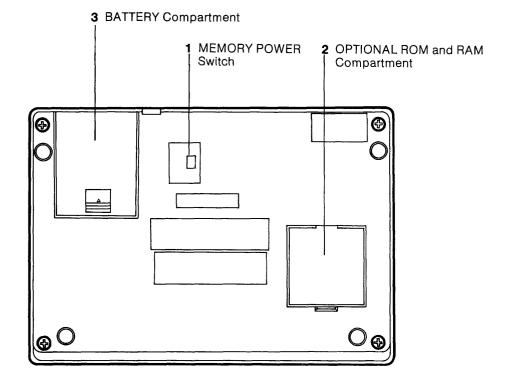

Figure 1-2. Rear View

- 1 **MEMORY POWER Switch:** This switch is used to prevent discharge of the internal Nickel-Cadmium battery, which is used for RAM back-up. The Tandy 102 will operate only when the power switch is set to ON. Set this switch to the OFF position when the Tandy 102 will not be used for a long period of time. Note that the RAM will not be backed up when this switch is set to the OFF position.
- 2 **Optional ROM and RAM Compartment:** An optional/extra ROM and RAM can be inserted into this compartment to enhance the Tandy 102 capabilities.
- **3 Battery Compartment:** When not connected to an AC power source, the Tandy 102 gets its power from four AA size batteries that must be installed in this compartment.

# **Internal View**

The Tandy 102 consists of three printed circuit boards:

- LCD PCB
- Keyboard PCB
- Main PCB

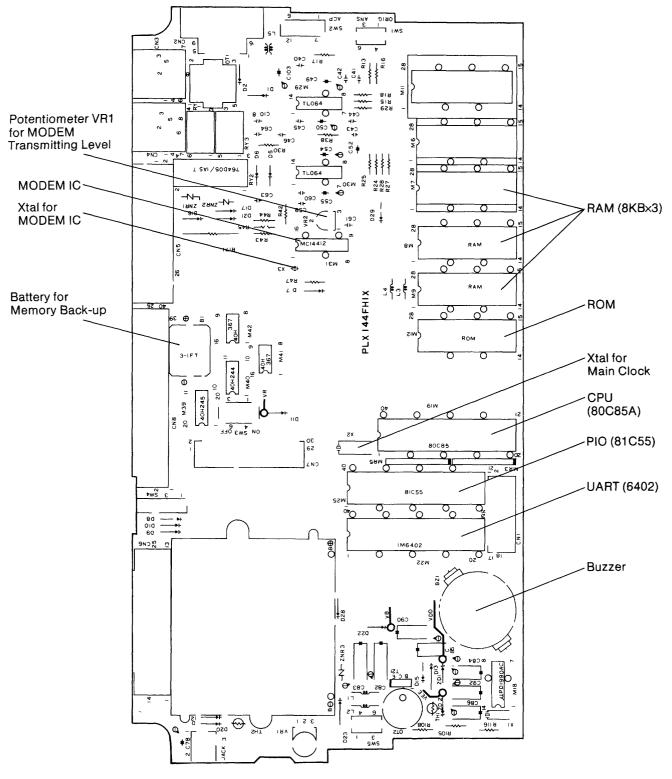

Figure 1-4. Main PCB (Bottom View)

# **II. DISASSEMBLY INSTRUCTIONS**

## Cases

- Disconnect the cables from the unit. Taking care not to scratch the LCD screen and key tops, turn the unit over and remove 4 screws A from the upper and lower cases.
- Remove the upper case. Therefore, the upper and lower cases are secured by snaps. Pull up the front of the upper case first, as shown below. Also, do not apply too much force when pulling it.

Figure 2-1. Top Case Removal

## **Keyboard and LCD PCBs**

- 1. Disconnect the flat cable from the connector on the keyboard PCB.
- 2. Remove the keyboard PCB.
- 3. Disconnect the flat cable from the connector on the LCD PCB.
- 4. Remove the LCD PCB.

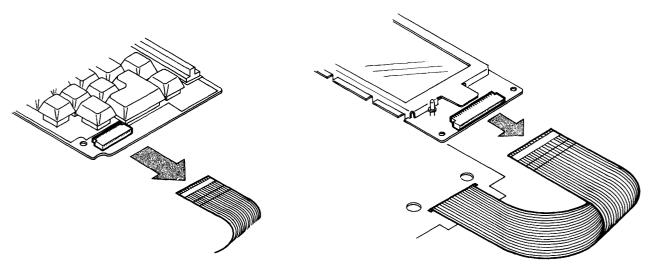

Figure 2-2. Keyboard and LCD PCBs Removal

# Main PCB

- 1. Remove the insulator board.
- 2. Remove 2 screws B securing the main PCB and bottom case.
- 3. Remove the main PCB.

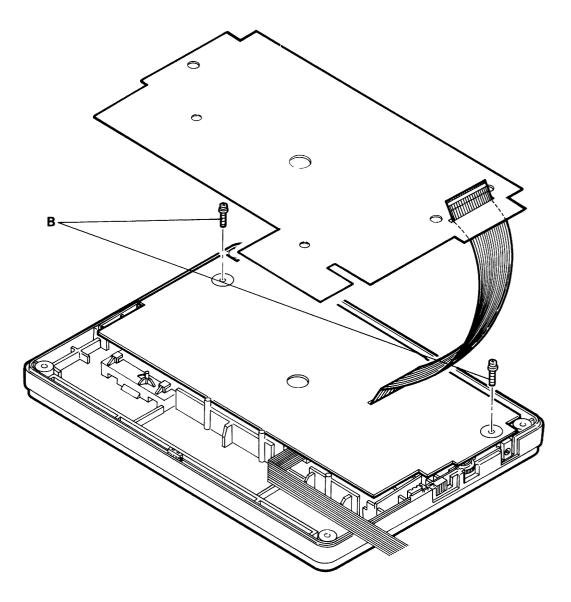

Figure 2-3. Main PCB Removal

# **III. MAINTENANCE**

# To Clean the Body and LCD Display

- 1. To avoid operational trouble, always keep the Tandy 102 clean.
- 2. Clean the body and the LCD screen using a soft, dry, lint-free cloth.
- 3. For tough stains, clean the body or the LCD screen with benzol.

### Caution: Do not use any solvents other than benzol.

# This is a blank page

# **IV. THEORY OF OPERATION**

# General

Figure 4-1 shows how this section is organized and highlights significant areas.

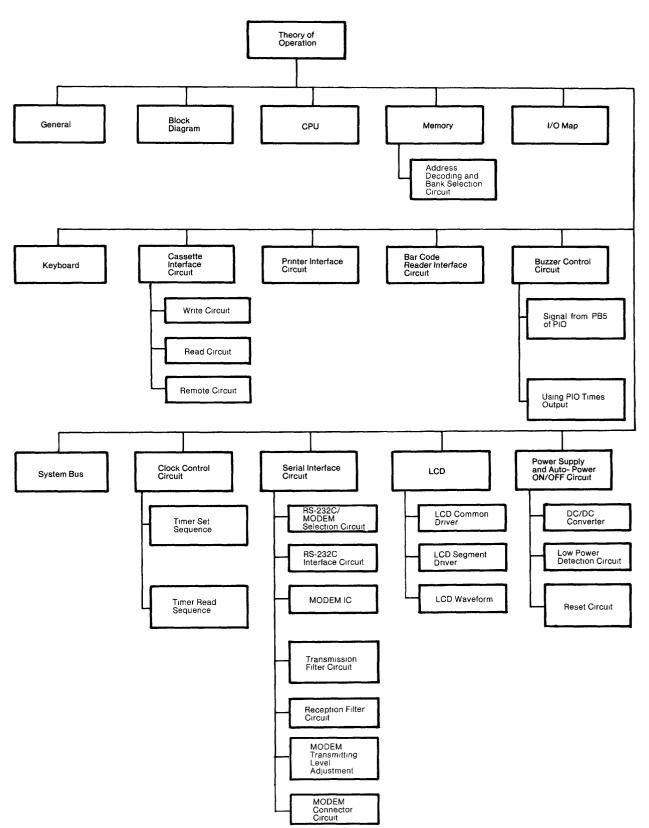

Figure 4-1. Organization of Section IV

# **Block Diagram**

The Tandy 102 has three principal LSIs.

• 80C85A CPU

This is the Central Processing Unit which controls all functions.

• 81C55 PIO

This is the Parallel Input/Output interface controller which controls the printer interface, keyboard, buzzer, clock and LCD interface.

• 6402 UART

This is the Universal Asynchronous Receiver Transmitter which controls the serial interface (RS-232C or MODEM).

The input/output for a cassette recorder and the input of the BCR are controlled by CPU directly through its SOD, SID and RST5.5 terminals.

ROM and RAMs are connected to the system bus. ROM is available only for alternative selection from Standard or Option.

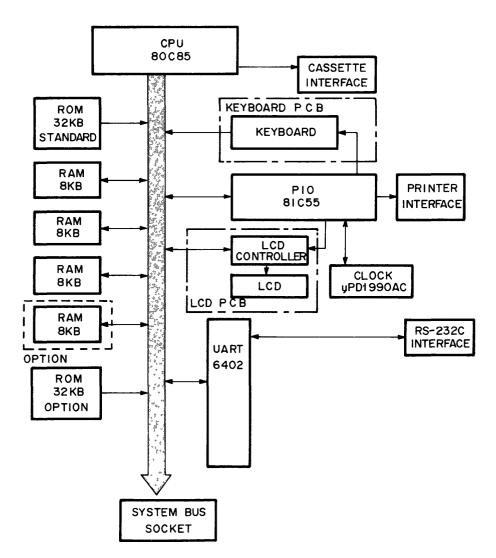

Figure 4-2. System Block Diagram

# CPU

The CPU is an 80C85A that runs at a clock speed of 2.4576 MHz. It is an 8-bit, parallel Central Processing Unit using C-MOS technology. The instruction set is fully compatible with the 8085A microprocessor. The 80C85A uses a multiplexed data bus. The CPU bus is divided into two sections- the 8-bit address bus named the A8-A15, and the 8-bit address and data bus named the AD0-AD7. The address bus signals are separated at M1, using the ALE\* (Address Latch Enable) signal.

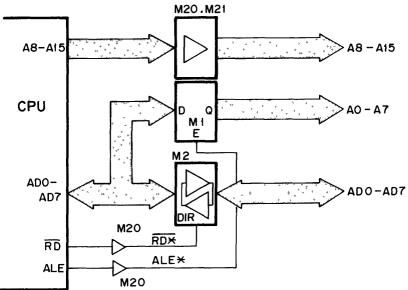

Figure 4-3. Functional Block Diagram of Bus Separation Circuit

## Memory

The memory of the Tandy 102 consists of a 32 KB standard ROM, three 8 KB C-MOS static RAMs and a 32 KB optional ROM.

The standard RAMs equipped in the Tandy 102 are M9, M8 and M7. By installing M6, memory capacity can be increased to 32 KB. The ROM used in the Tandy 102 is a 32 KB (256K bits) memory.

It is operated only by a +5V power source with an access time of 600 nsec (Max.).

The BASIC program and BIOS program which operate the LCD, printer etc. are stored in the standard ROM.

An optional ROM can be installed onto the special IC socket by removing the ROM cover on the bottom case of the Tandy 102. Various types of application programs are stored in the optional ROM.

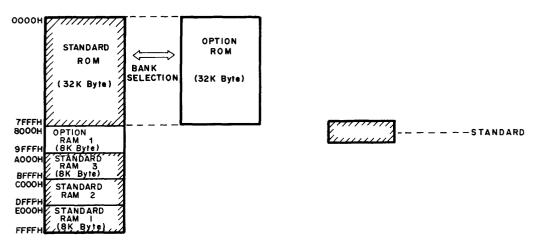

Figure 4-4. Memory Map

## **Address Decoding and Bank Selection Circuit**

Although four 8 KB static RAMs and two masked ROMs can be installed in the Tandy 102, six chip-select signals are required.

Because the RAMs are positioned from 8000H to FFFFH, and ROMs are positioned from 0000H to 7FFFH, address signal A15 selects the ROMs or RAMs at M5. At another section of M15, address signals A14 and A13 select each RAM corresponding to the memory map. The ROMs (both standard and optional) installed in the Tandy 102 are the 32 KB 1-chip type. As shown in the memory map, the address space is positioned from 0000H to 7FFFH.

The chip select signals are generated by the A15 and STROM signals. The AD0 is latched at M14 by the WR signal and Y6 signal, and then the STROM signal is generated.

The standard ROM is selected by the low level STROM signal and the optional ROM is selected by the high level STROM signal.

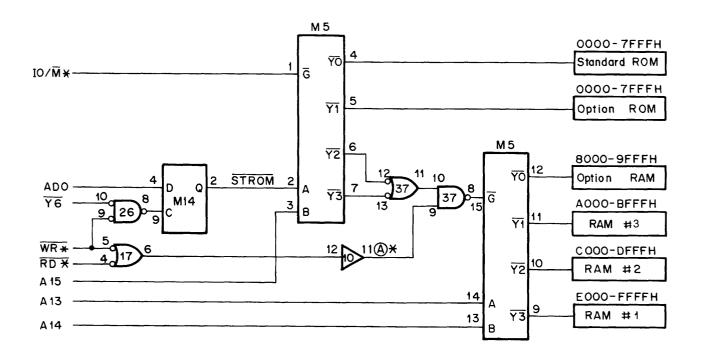

Figure 4-5. Address Decoding and Bank Selection Circuit

# I/O MAP

As shown in the figure below, the I/O address decoding circuit, consisting of M16, decodes address signals A12 to A15 and generates I/O selection signals  $\overline{Y0}$  to  $\overline{Y7}$ .

The application of the selection signals ( $\overline{Y0}$  to  $\overline{Y7}$ ) for the I/O devices are shown in Table 4-1. Table 4-2 shows the port address of the PIO.

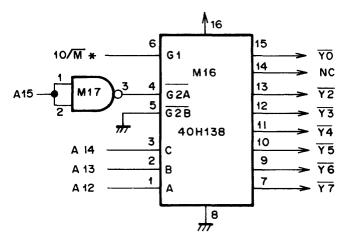

Figure 4-6. I/O Address Decoding Circuit

Address	Signal	Active Level	Application
00H – 7FH			Free area for an optional unit and other select sig- nals of various circuits made by user.
80 – 8FH	<u>Y0</u>	L	Device-select signal for optional I/O controller unit.
90H – 9FH	<u>¥2</u>	L	Enable signal for relay RY3 in MODEM connector interface circuit.
B0H – BFH	<u>Y3</u>	L	PIO (81C55) chip-select signal.
C0H – CFH	¥4	L	Enable signal for data input/output port of UART.
D0H – DFH	<u>¥5</u>	L	Enable signal to set various modes and read port of UART.
E0H – EFH	Y6	L	Enable signal for STROM and REMOTE, and input data from keyboard. Strobe signal for printer and clock.
F0H – FFH	¥7	L	Enable signal for LCD driver LSI.

### Table 4-1. I/O Map

Address	Port or Register

B4H or BCH	Timer register lower byte				
B5H or BDH	Timer register upper byte				
B6H, B7H, B8H and B9H	Not used				

Table 4-2. Port Address of PIO

# Keyboard

Key strobe signals are emitted from the PA0 to PA7 and PB0 terminals of the PIO. The return signals from the keyboard pass through the bus buffers (M15 and M3) and send to the CPU. The I/O address of the return signals is E0H-EFH.

The condition of pressing the "T" key is shown in the figure below.

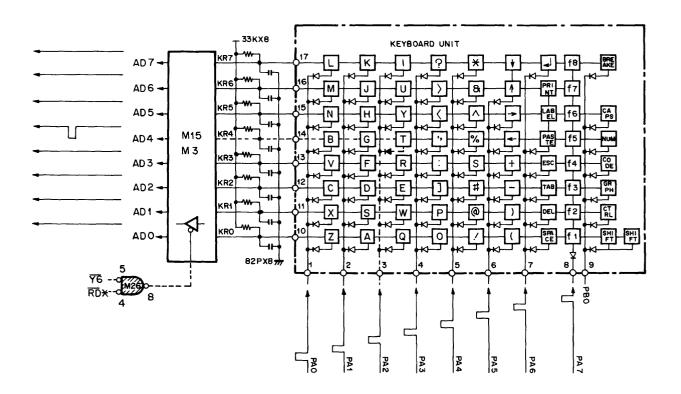

Figure 4-7. Condition of Pressing "T" Key

# **Cassette Interface Circuit**

The cassette interface circuit is subdivided into three sections:

- Write circuit
- Read circuit
- Remote circuit

## Write Circuit

The write circuit is accomplished in several steps. First, the serial data from the SOD terminal of the CPU is inverted by M34. Then, the DC component is removed by C63. Finally, the data passes through an integrator consisting of R51 and C64, and after voltage division, out to a cassette recorder AUX jack.

## **Read Circuit**

The signal input from the earphone jack of the cassette recorder passes through the clamp circuit consisting of D5 and D6, and then is input to the comparator circuit consisting of M30. Finally, the signal is converted into the digital signal and sent to the SID terminal of the CPU. In this circuit, D7 clamps the negative voltage output of the comparator.

## **Remote Circuit**

As a result of writing data "1" into bit 3 of the output port (M14) specified by I/O address E0H-EFH, the REMOTE signal is changed to H level.

Then, T6 is switched on and relay RY1 is energized. This causes the drive motor of the cassette recorder to operate.

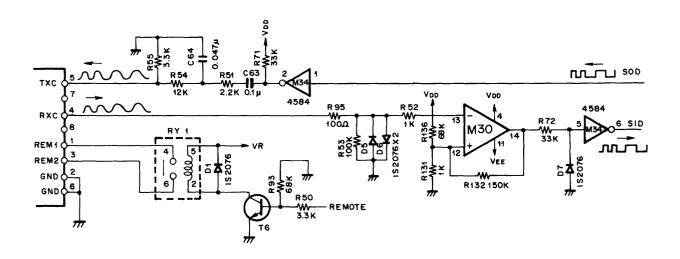

Figure 4-8. Cassette Interface Circuit

# **Printer Interface Circuit**

The printer interface circuit conforms to Centronics standards. As shown in Figure 4-9, the BUSY signal from the printer is read from the PC2 of the PIO. If the condition is not busy (PC2 = L), the 8-bit parallel data (PA0 - PA7) is sent to the printer. Then, by writing data "1" into bit 1 of the output port specified by I/O address E0H-EFH, the PSTB signal is sent to the printer.

As soon as the printer receives this PSTB signal, the BUSY signal is changed to H indicating that the printer is busy. The CPU then waits for a while until this BUSY signal becomes L. The printer prints the one character corresponding with the 8-bit parallel data. After completion of the one character printing, the printer sets the BUSY signal to L. Then, the CPU sends the next 8-bit parallel data. If the printer is in ONLINE condition, the BUSY signal is H and sent to the CPU, passing through the PC1 of the PIO. However, when in the OFFLINE condition, the BUSY signal is L and transmission of print data to the printer is inhibited by the CPU.

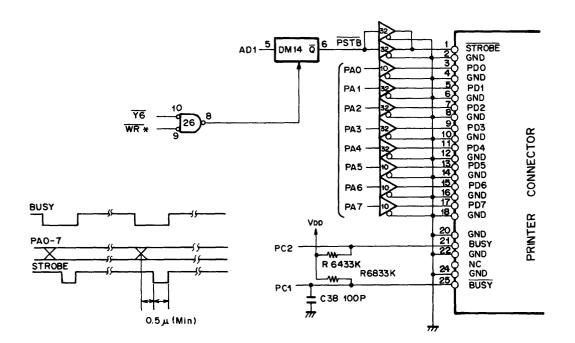

Figure 4-9. Printer Interface Circuit

# **Bar Code Reader Interface Circuit**

The input signal from the bar code reader is subjected to waveform shaping, inverted by the Schmitt-type inverter (M34), and then sent to the PC3 terminal of the PIO and the RST5.5 terminal of the CPU.

When the bar code reader reads the first white part of the bar code, a L level signal is generated, then inverted by M34 to notify the CPU of an interruption. As soon as RST5.5 interruption occurs, the CPU starts the data input operation, passing through the PC3 of the PIO. As the bar code reader is moved across the bars, H and L signals (which correspond to the white and black bars, respectively) are generated continuously and inversion signals are sent to the PC3 of the PIO as the serial input data stream.

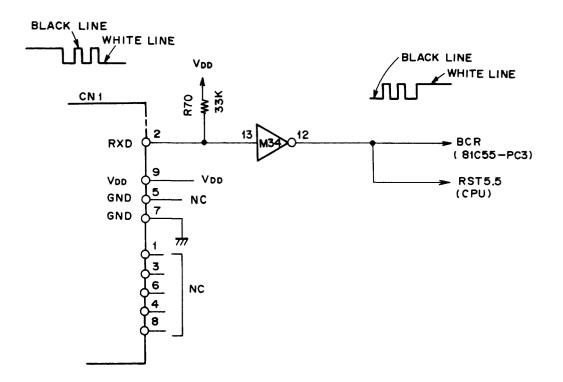

Figure 4-10. Bar Code Reader Interface Circuit

## **Buzzer Control Circuit**

There are two ways to operate the buzzer. One is to sound the buzzer with the specified frequency by emitting signals from the PB5 of the PIO and the other, by using the timer output signal of the PIO.

## Signal from PB5 of PIO

When the PB2 of the PIO is H, the buzzer sounds by repeated switching of the buzzer driving transistor. This is caused by H, L, H, L ... output signals from the PB5 synchronizing with the frequency for sounding the buzzer. This method is used for the BEEP command in BASIC.

## **PIO Timer Output**

In this method, the buzzer is sounded by setting the PIO timer in the square wave output mode. To write the value corresponding to the sound frequency, the CPU assigns B4H, B5H, BCH or BDH to the I/O port address. This frequency is assigned by the first parameter of the SOUND command in BASIC.

If the above procedures are completed, the TO terminal of the PIO outputs the square waves, and the PB2 of the PIO controls the length of the sound whenever the PB5 is "L". How long the sound is heard depends on the second parameter of SOUND command in BASIC.

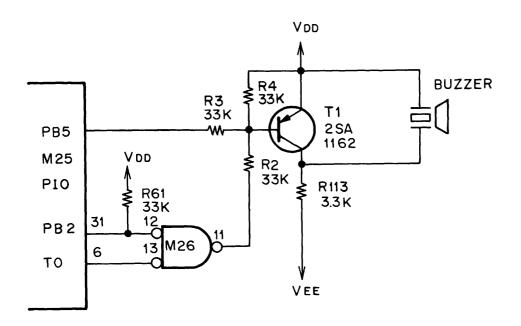

Figure 4-11. Buzzer Control Circuit

# System Bus

In order to expand the use of external devices, a 40-pin system bus connector is mounted on the back panel of the Tandy 102.

As shown in the Table 4-3, the address bus, data bus and control bus can be connected to the external devices passing through the drivers or receivers, thus making system expansion easy.

Pin No.	Signal	Description				
1	VDD	+5V power supply

Table 4-3.	S	vstem	Bus	Pin	Assignments
		<b>yo</b> toini	Duo		Accelentione

# **Clock Control Circuit**

A clock LSI ( $\mu$ PD1990AC) is used in the clock control circuit so that the time and date information can be set and read by the CPU.

As shown in Figures 4-12 to 4-13, when the Tandy 102 is in the operable condition (RESET is H), commands and data can be input and output to  $\mu$ PD1990AC from the CPU at will. In addition, because back-up power supply VB is applied to the  $\mu$ PD1990AC, the clock functions even when the Tandy 102 power switch is OFF.

The DATA IN, CLOCK and C0-C2 terminals of  $\mu$ PD1990AC are connected to the PA0-PA4 terminals of the PIO. The DATA OUT terminal is connected to the PC0 terminal of the PIO. The STB signal is provided from bit 2 of the output port made by M14.

The TP terminal of the  $\mu$ PD1990AC is connected to the RST7.5 terminal of the CPU. Square waves are output from the TP (4 ms cycle), and one key scan occurs every 4 ms because of the RST7.5 interruption to the CPU.

## **Time Set Sequence**

The CPU set  $\mu$ PD1990AC to the register shift mode with the "100" pattern of the C0-C2 and the strobe signal which is generated by the AD2,  $\overline{Y6}$  and  $\overline{WR^*}$  signals passing through M14. Then, the CPU sends the data of time and date information to the DATA IN terminal of  $\mu$ PD1990AC with timing clock PA3.

Finally, the CPU sets  $\mu$ PD1990AC to the time set mode with the "010" pattern of the C0-C2 and the strobe signal.

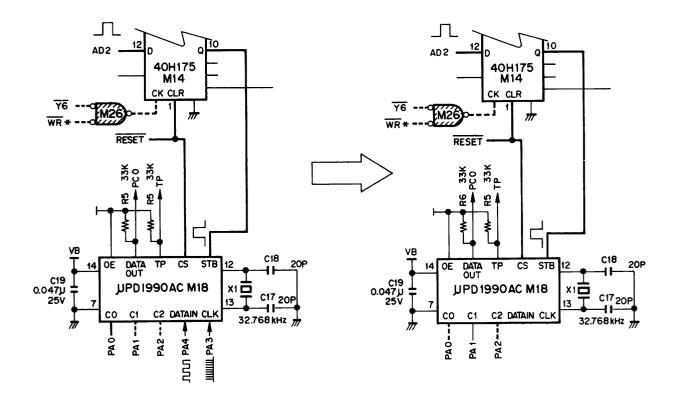

Figure 4-12. Time Set Sequence of  $\mu$ PD1990AC

## **Time Read Sequence**

The CPU sets the  $\mu$ PD1990AC to the time read mode with the "110" pattern of the C0-C2 and strobe signal.

Then the CPU sets the register shift mode with the "100" pattern of the C0-C2, and reads the data of time and date information from the DATA OUT terminal. At the same time, the CPU sends the PA3 signal passing through the PIO for the read timing clock.

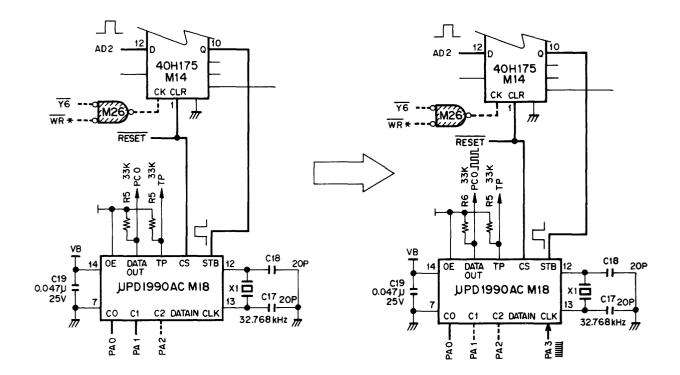

Figure 4-13. Time Read Sequence of  $\mu$ PD1990AC

# **Serial Interface Circuit**

The serial interface circuit supports asynchronous data transmission/reception. The heart of this circuit is the 6402 (UART). It performs the job of converting the parallel byte data from the CPU to a serial data stream including start, stop and parity bits.

For a more detailed description of how this IC performs these functions, refer to Appendix C of this manual.

Figure 4-14 shows the functional block diagram of the serial interface circuit. In this figure, the TO signal, basic timing clock for the UART, defines the transmission/reception baud rate.

To transmit and receive the serial data from external devices, the RS232C signal selects either MODEM or RS-232C interface. During the MODEM operation, the MODE signal switches either the originate mode or answer mode for the MODEM IC.

The serial interface circuit is subdivided into the following circuits:

- RS-232C/MODEM Selection Circuit
- RS-232C Interface Circuit
- MODEM IC
- Transmission Filter Circuit
- Reception Filter Circuit
- MODEM Connector Circuit

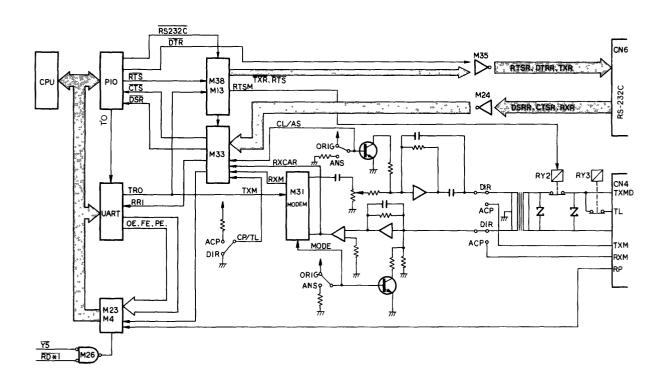

Figure 4-14. Functional Block Diagram of the Serial Interface

## **RS-232C/MODEM Selection Circuit**

The RS232C signal (PB3 terminal of the PIO) determines whether the serial port is to be used for RS-232C or for MODEM. When the RS232C signal is H, the serial port is used for MODEM. The reception signals, including the control signals, are demultiplexed at M33.

During the RS-232C mode, the CD (Carrier Detect) signal is not used. To make this condition, pin 14 of M33 is connected to the ground.

During the MODEM mode, the CL/AS signal is used as the sensing signal for the ORG/ANS switch, and CP/TL signal is used as the sensing signal for the ACP/DIR switch. In order to detect the carrier signal from the telephone line, the CD signal is connected to the RXCAR terminal of the MODEM IC.

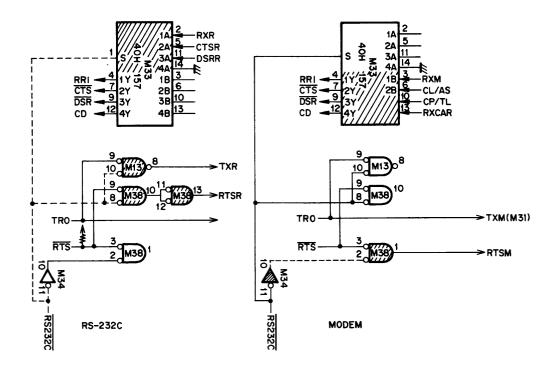

Figure 4-15. RS-232C/MODEM Selection Circuit

## **RS-232C Interface Circuit**

In the RS-232C transmission circuit, after the DC component is removed from the signals by the coupling capacitors, the signals are leveled to  $\pm 5V$  signals by the inverters connected in parallel, and then are output as RS-232C transmission signals.

In the RS-232C reception circuit, the DSRR, CTSR, and RXR signals from the external RS-232C line are subjected to waveform shaping and inverted by M24, and then converted to +5V or ground level signals by the diodes.

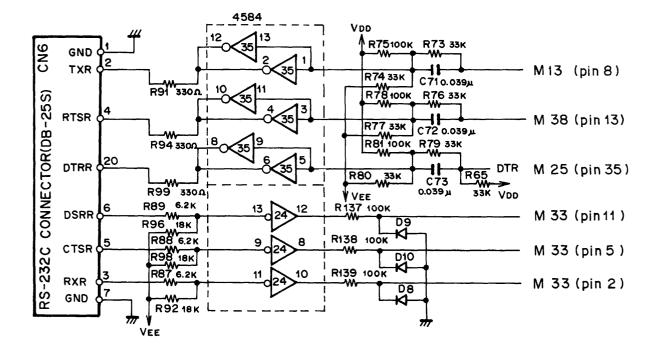

Figure 4-16. RS-232C Interface Circuit

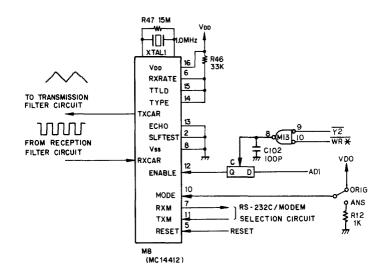

## MODEM IC

The Tandy 102 employs the IC MC14412 as a MODEM control device. This IC modulates/ demodulates data to be transmitted/received in accordance with frequencies suitable for originate or answer mode respectively.

The RXRATE and TYPE terminals of the MC14412 (M31) are pulled up to VDD. The baud rate is set to 300 bps and the U.S.Standard is selected. Since the ECHO and SELFTEST terminals are not needed, they are connected to ground.

The Q output (EN signal) of the M36 selected by bit 1 of the  $\overline{Y2}$  port is input to the ENABLE terminal when the MODEM mode is selected.

In addition, the signal detected by the ORG/ANS switch is input to the MODE terminal, and it switches between the ORIGINATE mode or ANSWER mode.

## **Transmission Filter Circuit**

The DC component of the carrier output from the TXCAR terminal is removed by C61. The signal level is adjusted by the potentiometer VR2. The signal then passes through the transmission band-pass filter and is sent to the telephone line or the acoustic coupler.

The transmission filter circuit is composed of an active filter (consisting of an operation amplifier) and the intermediate frequency of the active filter is 1170 Hz for the originate mode, and 2125 Hz for the answer mode. They are changed by switching T4 ON or OFF.

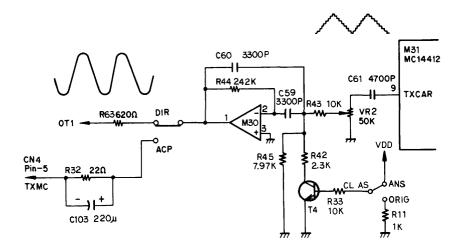

Figure 4-18. Transmission Filter Circuit

#### **Reception Filter Circuit**

As shown in Figure 4-19, the reception input signal is amplified when passing through coupling capacitor (C40), and amplified again as it passes through the 3-stage band-pass filter (composed of an active filter). The signal then passes through the comparator, and after being changed to a square wave, is input at the RXCAR terminal of the MC14412. Also, to check a carrier signal, this signal is input to the demultiplexer M33.

The intermediate frequencies of the 3-stage active filter are shown below. The switching of intermediate frequency for the originate and answer mode is accomplished by switching T2, T3 and T5 ON or OFF according to the ORG/ANS switch position, thus changing the input resistance of the filters.

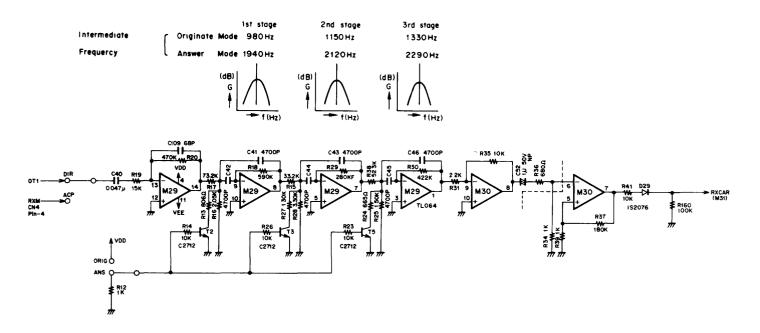

Figure 4-19. Reception Filter Circuit

#### Modem Transmitting Level Adjustment

- 1. Set the DIR/ACP switch to the DIR position.
- 2. Connect a 600-ohm dummy load between pin-3 (RXMD) and pin-7 (TXMD) of the MODEM connector (CN4).
- 3. Connect an AC voltmeter across the above dummy load.
- 4. Set up the Tandy 102 in BASIC mode and enter the following command to generates the carrier signal:

#### OUT 178,47 [ENTER] OUT 168,02 [ENTER]

5. Adjust VR2 so as to read -14 to -17 dBm on the AC voltmeter for both ANS and ORIG modes.

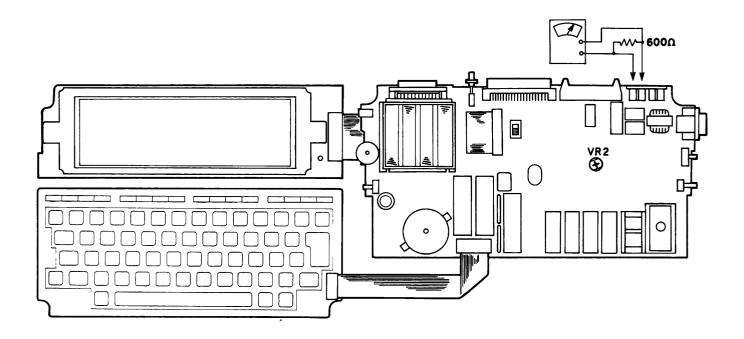

Figure 4-20. MODEM Adjustment

#### **MODEM Connector Interface Circuit**

When the acoustic coupler is used, the transmission and reception signals are directly connected to the connector (TXM, RXM). When the MODEM cable is used, they are connected to the secondary side of the driver transformer. The primary side of this transformer is connected to the telephone line via the connector (TXMD, RXMD).

The ACP/DIR switch is used in the MODEM mode, relay RY3 separates the telephone receiver audio signal (TL) to prevent interference. RY2, another relay, separates the MODEM circuit and the telephone at the conclusion of use in the MODEM mode and is also used as an automatic dialer for the pulse-type telephone line.

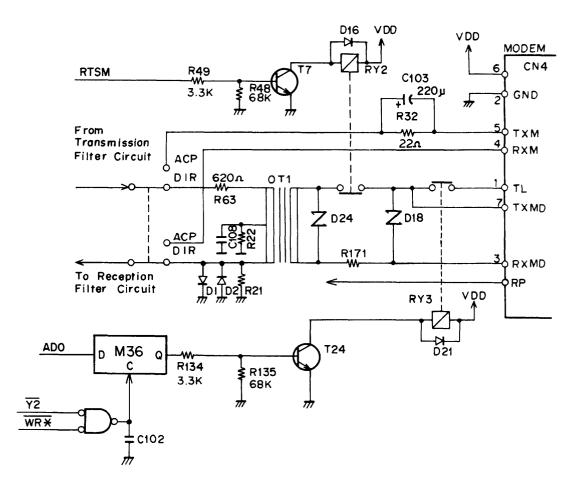

Figure 4-21. MODEM Connector Interface Circuit

# LCD

The LCD used in the Tandy 102 is composed of electrodes in a matrix arrangement (64 common signals and 480 segment signals) This part is subdivided into the following three sections:

- LCD Common Driver
- LCD Segment Driver
- LCD Waveform

For a more detailed description of how the LCD operates and its basic construction, refer to Appendix C of this manual.

### LCD Common Driver (HD44103)

The Tandy 102 uses two common driver ICs: M11 and M12. M11 controls the upper half of the LCD screen and M12 controls the lower half of the LCD screen. M11 and M12 are cascade connected, and a 1/32-duty backscan signal is made. By using C5 and R10 connected to the C and R terminals of M11, a timing signal is generated, which controls M12. M11 can be considered to be the master IC and M12 the slave.

The FRM signal defines the periodic frequency of one-screen display, and determines 70 Hz for the Tandy 102.

The MB signal is used for changing the driver signal to AC, because the continuous application of DC to the LCD would shorten the LCD element life.

The CL1 signal is used for the shift clock of the internal shift register.

The  $\phi$ 1 and  $\phi$ 2 signals are the clock signals for the HD44102 RAM operation.

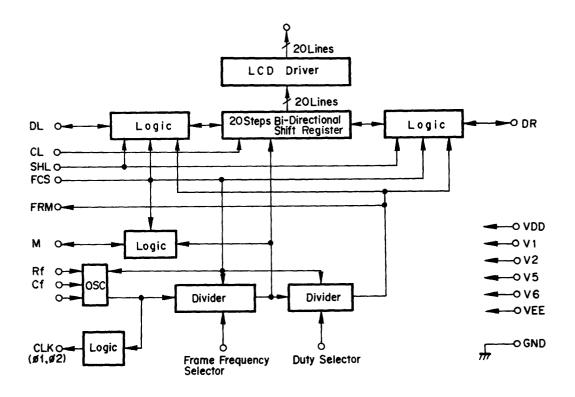

Figure 4-22. HD44103 Internal Logic Diagram

## LCD Segment Driver (HD44102)

M1-M10 (HD44102) on the LCD PCB are segment driver ICs that cause the display data sent from the main PCB to be memorized in the built-in RAM and automatically generate the LCD drive signal. One bit of data from the built-in RAM corresponds to one dot of illumination or non-illumination on the display. The driver outputs are 50 lines.

The transfer of the display data is accomplished by 8-bit parallel data. This IC has several types of commands. The D/I (H = data, L = command) signal distinguishes between commands and data. The Tandy 102 has 240 segments each (upper and lower), the segment driver outputs Y41 -Y50 are not used. The power supplied to these ICs, in addition to VDD (+5V) and VEE (-5V), also includes V1-V6.

VDD and VEE are the power supplies which operates the IC logic. V1-V6 operate the LCD driver signals.

V1-V6 are made up by the resistance splitting of R1, R2, R3, R4 and R5. By passing through the operational amplifier M13, the output impedance of the power supply is lessened.

Capacitors C3, C4, C6, C7 and C8 augment the peak current during LCD illumination.

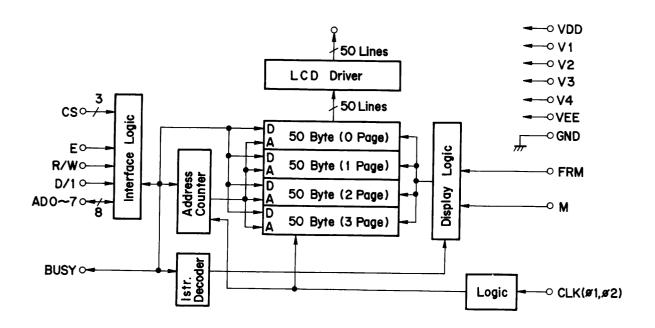

Figure 4-23. HD44102 Internal Logic Diagram

### LCD Waveform

In order to drive the liquid-crystal element by the 1/32 duty line-sequential drive method, the LCD of the Tandy 102 makes sequential selection of the 32 scanning electrodes.

For each dot, the display signal passes through the signal electrode and is applied 32 times for one display.

At this point, the signal is necessary at each dot only one time. The signals for the other 31 times correspond to other dots on the same signal electrode.

The maximum voltage applied to common electrode and segment electrode is the potential difference between V1 and V2.

In addition, "a" is the bias coefficient which determines, from the standpoint of contrast, the maximum ratio between the illumination voltage and the non-illumination voltage.

When that ratio is the greatest in relation to the effective ON and OFF voltages, a = 6.66. Thus, for V1, V2, V3, V4, V5 and V6:

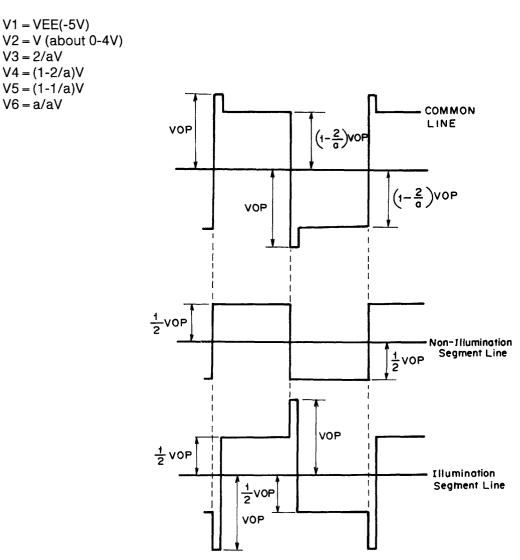

Figure 4-24. LCD Waveform

# **Power Supply Circuit**

The Tandy 102 logic circuit uses +5V for VDD, -5V for VEE and +4 to +5V for VB. These voltages are supplied by the DC/DC converter. Also, the power supply circuit has the automatic power off function and reset circuit.

### **DC/DC Converter Circuit**

OT2 is a converter transformer which oscillates T21 and T22 and generates voltages at the secondary side of the transformer. At the same time the power is switched ON, a very slight collector current flows to T21 and T22. As the current flowing through OT2 is increased, the voltage induced between pin 8 and pin 9 of the converter transformer causes pin 9 to be positive. The positive voltage is applied to the base of T22 passing through R126 and C81 to activate T21 and T22.

Fully charged, C81 stops the primary current. The secondary magnetic field begins to collapse, reversing the polarity of the induced voltage, causing pin 9 to be negative. By being applied to the base of T22 through C81, this voltage is used to turn OFF T21 and T22, as C81 discharges. Discharged C81 allows the transistor to turn ON again to repeat this cycle. The switching frequency is determined by R126 and C81.

The output of this circuit is derived from the secondary winding. VEE is from pin 9, rectified by D15, filtered by C85, and VDD is from pin 7, rectified by D13, filtered by C84.

Also, VDD is fed back to the base of T13 through zener diode D4 to maintain VDD of +5V.

### **Low Power Detection Circuit**

The low power detection circuit illuminates an LED warning lamp when the battery voltage decreases. If it continues to decrease, the system power will be switched OFF just before the voltage becomes so low that the converter cannot operate.

There are about 20 minutes between the time when the LED lamp illuminates and the system is switched OFF.

Battery voltage is detected by splitting the resistance of R105, R108, R144 and R116. When the battery voltage (VR) becomes 4.2V  $\pm$  0.1V, T16 is switched OFF. T17 is switched ON, T19 is driven, and the LED illuminates.

When VL becomes  $3.7V \pm$ , T14 is switched OFF, T15 is switched ON, and the LPS signal changes from H to L. This signal is inverted by M34 and fed to the TRAP terminal of the CPU. If the CPU acknowledges this signal, it sends the PCS signal passing through the PB4 of the PIO after the internal operations.

When the PCS becomes H, the Q output of M28 becomes H, T20 operates and the oscillation of the converter is stopped.

If there is no operation for 10 minutes or more (awaiting a command for 10 minutes or more), the PCS is output from the PB4 of the PIO.

When the power switch is switched OFF, T18 is switched OFF, the RESET terminal of M28 becomes H and oscillation is resumed by switching the power switch ON. If, however, the power is reduced by the PCS signal, a battery replacement is necessary.

### **RESET Circuit**

This circuit supplies the RESET signal and also the RAM RST signal as the protecting signal for the contents of the RAM when the power decreases. C78 and R103 delay the introduction of input power so that T11 is switched ON and T10 is switched OFF after VDD is activated, with the result that the RESET signal changed from L to H. In the same way, the RAM RST signal is generated by T9 and changes from H to L. Thermistor TH2 suppresses the RESET signal fluctuations due to temperature.

T25 receives the signal from the Q terminal of M28 during automatic power OFF, short-circuiting both ends of C78, and resets the system. The RESET signal is active L and the RAM RST signal is active H.

# V. TROUBLESHOOTING

# **General Guidance**

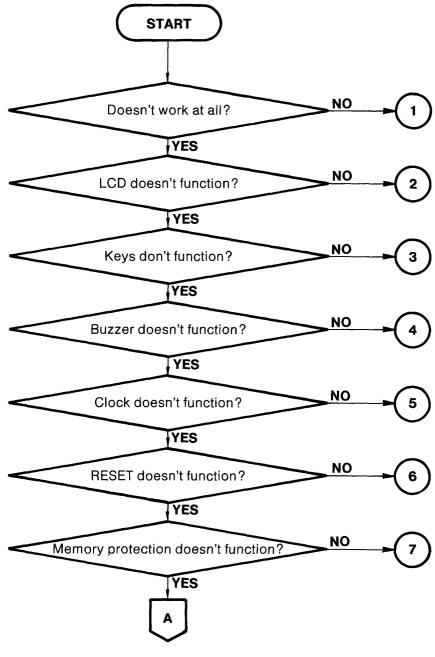

#### How to Make Use of This Section

If you have a problem or have to repair the Tandy 102, this section will be very helpful to you. If the location or condition of the malfunctions are clear, for instance, the buzzer does not function, refer to the flowchart in the TROUBLESHOOTING GUIDE and find the number circled. Then, you will be able to find the necessary information, such as corresponding ICs and transistors, for malfunction repair.

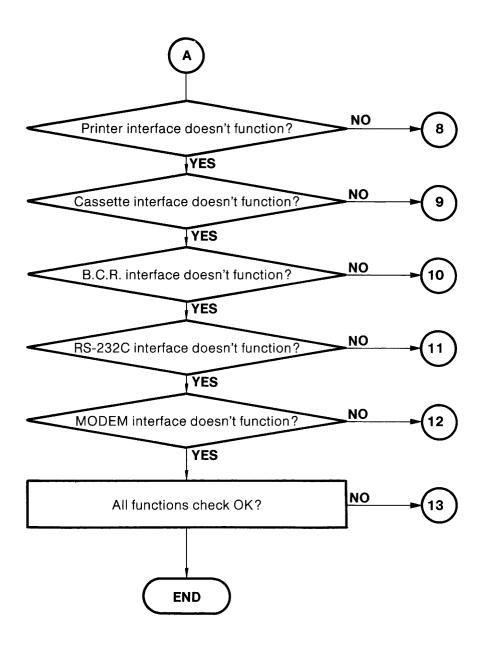

After you complete the malfunction repair, re-check each functional item according to the CHECK LIST.

You can make use of the CHECK LIST even if the location and condition of the malfunction are not clear.

## **Troubleshooting Guide**

## **Checking Procedure**

1. Doesn't work at all

- Check the power.
- Check to be sure that the batteries are in and that the AC adapter is connected.
- Is the memory back-up power switch ON?
- Is the power switch ON?

Check the DC/DC converter circuit.

 Is 3.6 – 8V applied to pin 1 of the converter transformer? (If not, check C82, C83, battery contacts and adapter jack.)

• Check all output voltages.

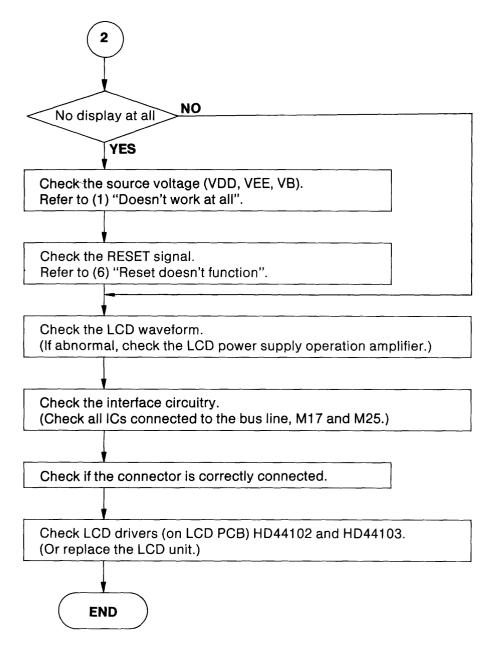

- a) VDD ..... +5V (if not, check D13, C84 and ZD1)
- b) VEE ..... –5V (if not, check D15, C85 and ZD2)
- c) VB ..... +5V (if not, check T27 and T28)
- Is T21 oscillating? (If not, check T22, T13, C81, R126, R127, R140 and T20.)

Check the **RESET** signal.

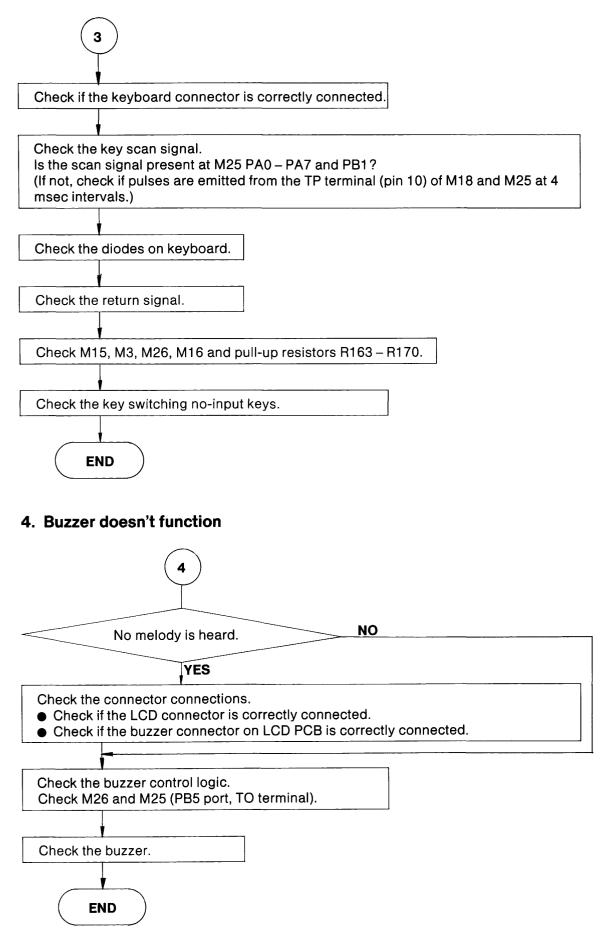

- Is it high level (+2.2V 5.3V)? If not, check T10, T11, T25, T9 RESET signal.
   Is it low level (0.8V - 0.3V)?
- If not, check T10, T11, T25, T9 RESET signal.
- Check the CPU clock frequency. (X1 terminal = 4.9152 MHz; CLK terminal = 2.4576 MHz) (If not, check X2 and M19.)
- Try replacing the LCU unit.
- Check all ICs.

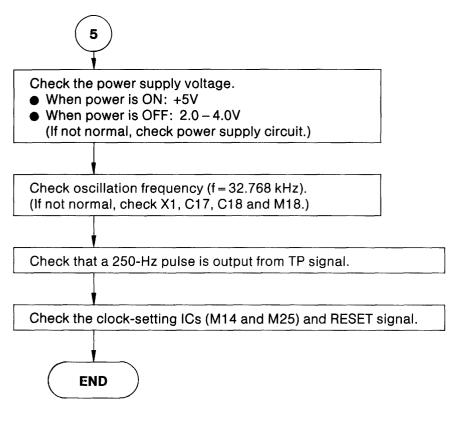

#### 2. LCD doesn't function

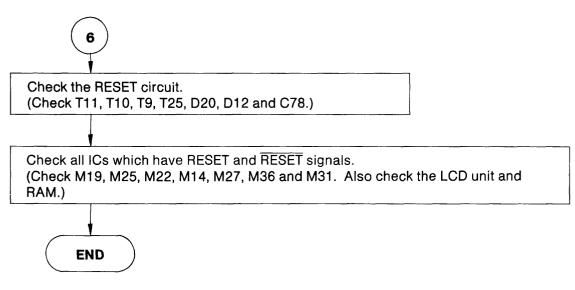

## 3. Key doesn't function

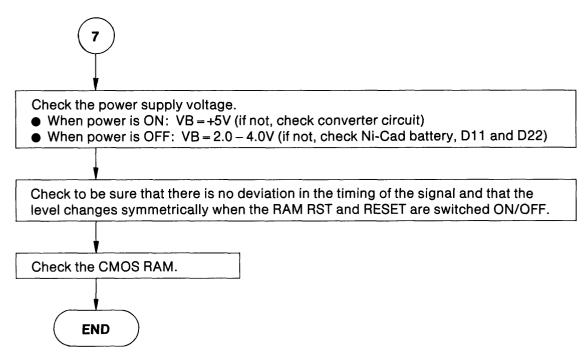

#### 5. Clock doesn't function

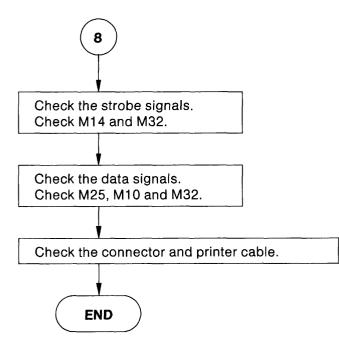

#### 6. Reset doesn't function

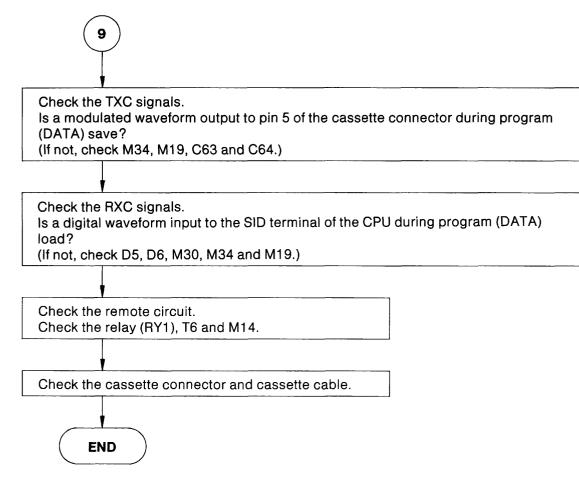

### 7. Memory protection doesn't function

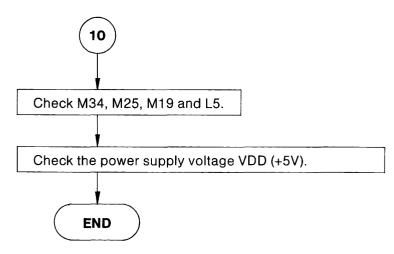

#### 8. Printer interface doesn't function

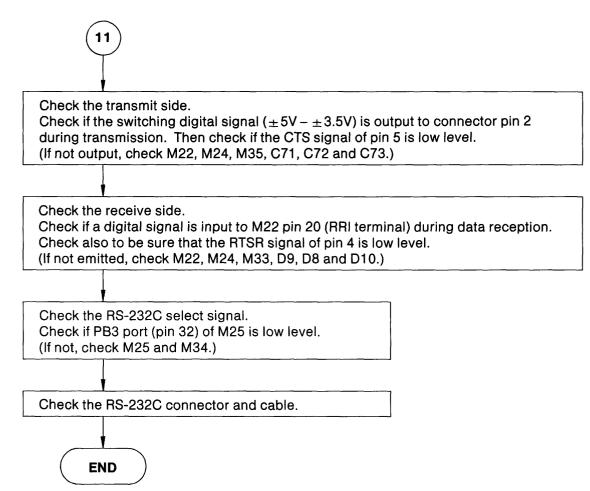

#### 8. Cassette interface doesn't function

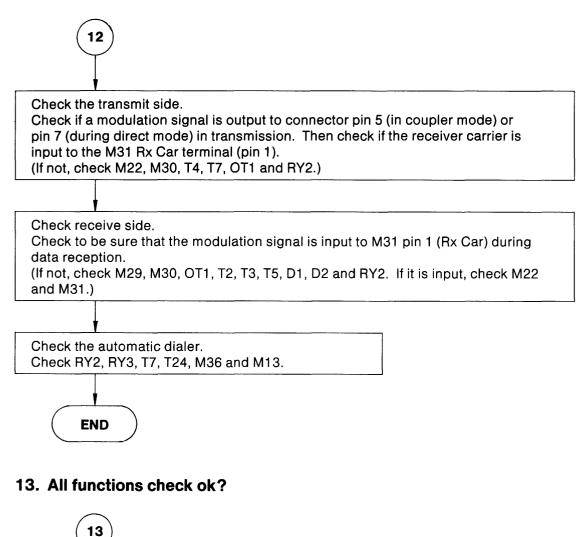

#### 10. B.C.R. interface doesn't function

#### 11. RS-232C interface doesn't function

#### 12. Modem interface doesn't function

# **Check List**

After completing all repairs and adjustments, check all functions according to the Test Program as shown below. A model 100 diagnostics tape available through Radio Shack can also be used. Before beginning the checking, initialize the RAM contents by performing a cold start. Refer to "(4) Reset function test".

#### (1) Buzzer and LCD check (in BASIC mode)

10 FOR 1 = 0 TO 255 20 PRINT CHRS (1); 30 NEXT 1 40 END After 1 beep and the LCD display clears, all characters are displayed.

#### (2) Clock test (in BASIC mode)

- (a) Setting the year, month, date, day, hour, minute and second: Year, month, date setting: Date\$ = "MM/DD/YY" Day setting: DAY\$ = "day" (example: Sunday = SUN) Hour, minute, second setting: TIME\$ = "HH: MM: SS"
- (b) Confirmation of set data Return to the menu by executing the MENU command. Then, check to be sure that the calendar data changes to set data.

#### (3) Key board test

Refer to the character code table in Appendix B and check that all keys can be input.

#### (4) Reset function test (memory protection test)

(a) Warm start

Press the RESET switch on the rear of the case or switch the POWER switch to ON, and check that initialization is made. Also check that the saved USER files are not erased.

(b) Cold start

While pressing the CTRL and PAUSE keys, press the RESET switch and check that all USER files are erased.

#### (5) Printer interface test (in BASIC mode)

Input the characters to be printed out on the LCD display. When the hard copy key PRINT is pressed, the displayed characters will all be printed out.

#### (6) Cassette interface test (in BASIC mode)

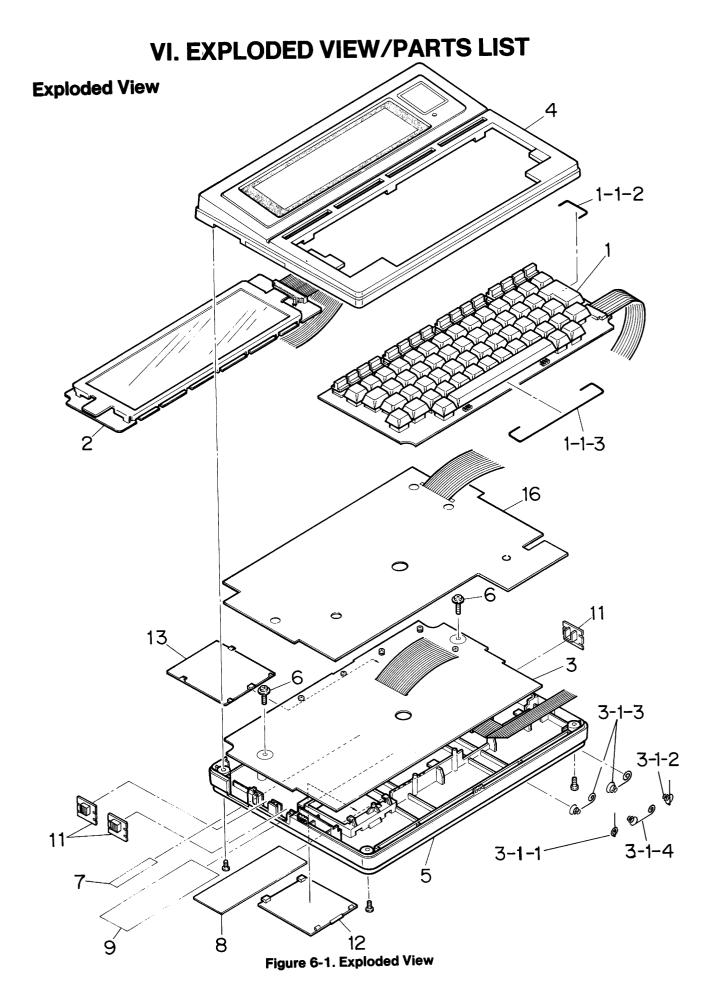

Input a suitable program, save it on cassette (by CSAVE "file name"), and then read out the saved program (by CLOAD "file name") and check it.

#### (7) RS-232C and MODEM tests.

Prepare two units and make the tests while referring to the section on communications in the Operation Manual.

# **APPENDIX A /INSTALLATION**

## Installation of Optional RAM and ROM

- Using a coin, remove the RAM and ROM cover on the bottom case.
- Insert the optional RAM into the IC socket marked M6.
  Insert the optional ROM into the IC socket marked M11.
  - Optional RAM

# **APPENDIX C/TECHNICAL INFORMATION**

## C-1. 80C85A

### **General Description**

The 80C85A is a complete 8-bit, parallel central processor implemented in silicon gate C-MOS technology and compatible with 8085A.

It is designed with the same processing speed and lower power consumption compared with 8085A, thereby offering a high level of system integration.

The 80C85A uses a multiplexed address/data bus. The address is split between the 8-bit address bus and the 8-bit data bus.

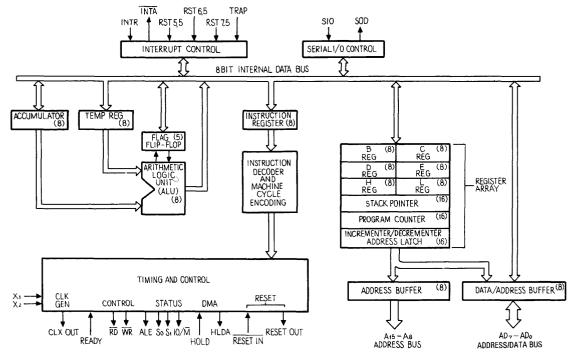

Figure C-1. Functional Block Diagram

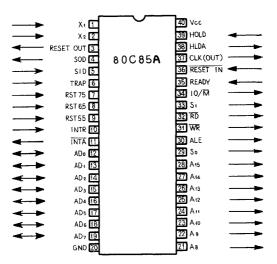

Figure C-2. Pin Configuration of 80C85A

### **Functional Pin Description**

#### **A**<sub>8</sub> – **A**<sub>15</sub> (Output, 3-state)

Address Bus: The most significant 8 bits of the memory address or the 8 bits of the I/O address, 3-stated during Hold and Halt modes and during RESET.

#### **AD**<sub>0</sub> – **AD**<sub>7</sub> (Input/Output, 3-state)

Multiplexed Address/Data Bus: Lower 8 bits of the memory address (or I/O address) appear on the bus during the first clock cycle (T state) of a machine cycle. It then becomes the data bus during the second and third clock cycles.

#### ALE (Output)

Address Latch Enable: It occurs during the first clock state of a machine cycle and enables the address to latched onto the on-chip latch of the peripherals. The falling edge of ALE is set to guarantee setup and hold times for the address information. The falling edge of ALE can also be used to strobe the status information. ALE is never 3-stated.

#### $S_0$ , $S_1$ and $IO/\overline{M}$

Machine cycle status:

IO/M	Sı	S₀	States	10/M	Sı	So	States
0	0	1	Memory write	1	1	1	Interrupt Acknowledge
0	1	0	Memory read		0	0	Halt . = 3-state
1	0	1	I/O write		×	×	Hold (high impedance)
1	1	0	I/O read		×	×	Reset ×=unspecified
0	1	1	Opcode fetch				

 $S_1$  can be used as an advanced R/W status. IO/ $\overline{M}$ ,  $S_0$  and  $S_1$  become valid at the beginning of a machine cycle and remain stable throughout the cycle. The falling edge of ALE may be used to latch the state of these lines.

#### RD (Output, 3-state)

READ control: A low level on RD indicates the selected memory or I/O device is to be read and that the Data Bus is available for the data transfer, 3-stated during Hold and Halt modes and during RE-SET.

#### WR (Output, 3-state)

WRITE control: A low level on WR indicates the data on the Data Bus is to be written into the selected memory or I/O location. Data is set up at the trailing edge of WR, 3-stated during Hold and Halt modes and during RESET.

#### **READY** (Input)

If READY is high during a read or write cycle, it indicates that the memory or peripheral is ready to send or receive data. If READY is low, the CPU will wait an integral number of clock cycles for READY to go high before completing the read or write cycle. READY must conform to specified setup and hold times.

#### HOLD (Input)

HOLD indicates that another master is requesting the use of the address and data buses. The CPU, upon receiving the hold request, will relinquish the use of the bus as soon as the completion of the current bus transfer. Internal processing can continue. The processor can regain the bus only after the HOLD is removed. When the HOLD is acknowledged, the Address, Data, RD, WR, and IO/M lines are 3-stated.

#### HLDA (Output)

HOLD ACKNOWLEDGE: Indicates that the CPU has received the HOLD request and that it will relinguish the bus in the next clock cycle. HLDA goes low after the Hold request is removed. The CPU takes the bus one half clock cycle after HLDA goes low.

#### INTR (Input)

INTERRUPT REQUEST: As a general purpose interrupt, it is sampled only during the next to the last clock cycle of an instruction and during Hold and Halt states. If it is active, the Program Counter (PC) will be inhibited from incrementing and an INTA will be issued. During this cycle a RESTART or CALL instruction can be inserted to jump to the interrupt service routine. The INTR is enabled and disabled by software. It is disabled by Reset and immediately after an interrupt is accepted.

#### **INTA** (Output)

INTERRUPT ACKNOWLEDGE: Used instead of (and has the same timing as)  $\overline{\text{RD}}$  during the instruction cycle after an INTR is accepted.

#### RST 5.5, RST 6.5, RST 7.5 (Input)

RESTART INTERRUPTS: These three inputs have the same timing as INTR, except that they cause an internal RESTART to be automatically inserted.

The priority of these interrupts is ordered as shown in Table C-1. These interrupts have a higher priority than INTR. In addition, they may be individually masked out using the SIM instruction.

#### TRAP (Input)

Trap interrupt is a nonmaskable RESTART interrupt. It is recognized at the same timing as INTR or RST 5.5 - 7.5. It is unaffected by any mask or Interrupt Disable. It has the highest priority of any interrupt. (See Table C-1.)

#### **RESET IN** (Input)

Sets the Program Counter to zero and resets the Interrupt Enable and HLDA flip-flops. The data and address buses and the control lines are 3-stated during RESET and because of the asynchronous nature of RESET, the processor's internal registers and flags may be altered by RESET with unpredictable results. RESET IN is a Schmitt-triggered input, allowing connection to an R-C network for power-on RESET delay. The CPU is held in the reset condition as long as RESET IN is applied.

#### **RESET OUT** (Output)

Indicates the CPU is being reset. Can be used as a system reset. The signal is synchronized to the processor clock and lasts an integral number of clock periods.

#### **X**<sub>1</sub>, **X**<sub>2</sub> (Input)

 $X_1$  and  $X_2$  are connected to a crystal to drive the internal clock generator.  $X_1$  can also be an external clock input from a logic gate. The input frequency is divided by 2 to give the processor's internal operating frequency.

#### CLK (Output)

Clock Output for use as a system clock. The period of CLK is twice the X<sub>1</sub>, X<sub>2</sub> input period.

#### SID (Input)

Serial input data line. The data on this line is loaded into accumulator bit 7 whenever a RIM instruction is executed.

#### SOD (Output)

Serial output data line. The output SOD is set or reset as specified by the SIM instruction.

#### Vcc

+5 volt supply.

#### GND

Ground reference.

Name	Priority	Address Branched To (1) When Interrupt Occurs	Type Trigger
TRAP	1	24H	Rising edge and high level until sampled.
RST 7.5	2	ЗСН	Rising edge (latched).
RST 6.5	3	34H	High level until sampled.
RST 5.5	4	2CH	High level until sampled.
INTR	5	(2)	High level until sampled.

**Notes:** (1) The processor pushes the PC on the stack before branching to the indicated address.

(2) The address branched depends on the instruction provided to the CPU when the interrupt is acknowledged.

#### Table C-1. Interrupt Priority, Restart Address and Sensitivity

#### Function

The 80C85A has twelve addressable 8-bit registers. Four can function only as two 16-bit register pairs. Six others can be used interchangeably as 8-bit registers or a 16-bit register pair. The 80C85A register set is as follows:

Mnemonic	Register	Contents
ACC or A	Accumulator	8-bits
PC	Program Counter	16-bit address
BC, DE, HL	General-Purpose Register; data pointer (HL)	8-bit $\times$ 6 or 16-bits $\times$ 3
SP	Stack Pointer	16-bit address
Flags or F	Flag Register	5 flag (8-bit space)

The 80C85A uses a multiplexed Data Bus. The address is split between the higher 8-bit Address Bus and the lower 8-bit Address/Data Bus. During the first T state (clock cycle) of a machine cycle, the low order address is sent out on the Address/Data Bus. These lower 8-bits may be latched externally by the Address Latch Enable signal (ALE). During the rest of the machine cycle, the data bus is used for memory or I/O data.

The 80C85A provides RD, WR, S<sub>0</sub>, S<sub>1</sub> and IO/M signals for bus control. An Interrupt Acknowledge signal (INTA) is also provided. Hold and all Interrupts are synchronized with the processor's internal clock. The 80C85A also provides Serial Input Data (SID) and Serial Output Data (SOD) lines for a simple serial interface.

In addition to these features, 80C85A has three maskable, vector interrupt pins and one nonmaskable TRAP interrupt.

### Interrupt and Serial I/O

The 80C85A has 5 interrupt inputs: INTR, RST 5.5, RST 6.5, RST 7.5, and TRAP. INTR is identical in function to the 8080A INT. Each of the three RESTART inputs, 5.5, 6.5, and 7.5, has a programmable mask. TRAP is also a RESTART interrupt but it is nonmaskable.

The three maskable interrupts cause the internal execution of RESTART (saving the program counter in the stack and branching to the RESTART address) if the interrupts are enabled and if the interrupt mask is not set. The nonmaskable TRAP causes the internal execution of a RESTART vector independent of the state of the interrupt enable or masks. (See Table C-1.)

There are two different types of inputs in the restart interrupts. RST 5.5 and RST 6.5 are high levelsensitive like INTR (and INT on the 8080A) and are recognized with the same timing as INTR. RST 7.5 is rising edge-sensitive. For RST 7.5, only a pulse is required to set an internal flip-flop which generates the internal interrupt request. The RST 7.5 request flip-flop remains set until the request is serviced. Then it is reset automatically. This flip-flop may also be reset by using the SIM instruction or by issuing a RESET IN to the 80C85A. The RST 7.5 internal flip-flop will be set by a pulse on the RST 7.5 pin even when the RST 7.5 interrupt is masked out.

The interrupts are arranged in a fixed priority that determines which interrupt is to be recognized if more than one is pending as follows: TRAP-highest priority, RST 7.5, RST 6.5, RST 5.5, INTR-lowest priority. This priority scheme does not take into account the priority of a routine that was started by a higher priority interrupt. RST 5.5 can interrupt an RST 7.5 routine if the interrupts are re-enabled before the end of the RST 7.5 routine.

The TRAP interrupt is useful for catastrophic events such as power failure or bus error. The TRAP input is recognized just as any other interrupt but has the highest priority. It is not affected by any flag or mask. The TRAP input is both edge and level sensitive. The TRAP input must go high and remain high until it is acknowledged. It will not be recognized again until it goes low, then high again. This avoids any false triggering due to noise or logic glitches. Figure C-3 illustrates the TRAP interrupt request circuitry within the 80C85A. Note that the servicing of any interrupt (TRAP, RST 7.5, RST 6.5, RST 5.5, INTR) disables all future interrupts (except TRAPs) until an El instruction is executed.

The TRAP interrupt is special in that it disables interrupts, but preserves the previous interrupt enable status. Performing the first RIM instruction following a TRAP interrupt allows you to determine whether interrupts were enabled or disabled prior to the TRAP. All subsequent RIM instructions provide current interrupt enable status. Performing a RIM instruction following INTR or RST 5.5-7.5 will provide current Interrupt Enable status, revealing that Interrupts are disabled.

The serial I/O system is also controlled by the RIM and SIM instructions. SID is read by RIM, and SIM sets the SOD data.

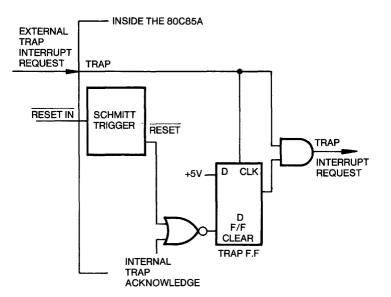

Figure C-3. Trap and RESET IN

### **Basic System Timing**

The 80C85A has a multiplexed Data Bus. ALE is used as a strobe to sample the lower 8-bits of address on the Data Bus. Figure C-4 shows an instruction fetch, memory read and I/O write cycle (as would occur during processing of the OUT instruction). Note that during the I/O write and read cycle that the I/O port address is copied on both the upper and lower half of the address.

There are seven possible types of machine cycles. Which of these seven takes place is defined by the status of the three status lines  $(IO/\overline{M},S_1,S_0)$  and the three control signals ( $\overline{RD}$ ,  $\overline{WR}$ , and  $\overline{INTA}$ ). (See Table C-2.) The status line can be used as advanced controls (for device selection, for example), since they become active at the T<sub>1</sub> state, at the outset of each machine cycle. Control lines  $\overline{RD}$  and  $\overline{WR}$  become active later, at the time when the transfer of data is to take place, so are used as command lines.

A machine cycle normally consists of three T states, with the exception of OPCODE FETCH, which normally has either four or six T states (unless WAIT or HOLD states are forced by the receipt of READY or HOLD inputs). Any T state must be in one of ten possible states, shown in Table C-3.

Mashi	on Quela		Status		Control		
Machir	ne Cycle	IO/M	Sı	So	RD	WR	INTA
Opcode Fetch	(OF)	0	1	1	0	1	1
Memory Read	(MR)	0	1	0	0	1	1
Memory Write	(MW)	0	0	1	1		1
I/O Read	(IOR)	1	1	0	0	1	1
I/O Write	(IOW)	1	0	1	1	0	1
Acknowledge of IN	TR (INA)	1	1	1	1	1	0
Bus Idle	(BI): DAD ACK. OF	0	1	0	1	1	1
	RST, TRAP HALT	1 TS	1 0	1 0	1 TS	1 TS	1

#### Table C-2. 80C85A Machine Cycle Chart

Figure C-4. 80C85A Basic System Timing

## C-2. 81C55

### **General Description**

The MSM81C55RS/GS is a 2K bit static RAM (256 byte) with parallel I/O ports. It uses silicon gate CMOS technology and consumes a standby current of 100 micro amperes maximum while the chip is not selected. Featuring a maximum access time of 400 ns, the MSM81C55RS/GS can be used in an 80C85A system without using wait states. The parallel I/O consists of two 8-bit ports and one 6-bit port (both general purpose). The MSM81C55RS/GS also contains a 14-bit programmable counter/timer which may be used for sequence-wave generation or terminal countpulsing.

## **Functional Pin Description**

#### **RESET** (Input)

A high level input to this pin resets the chip, placing all three I/O ports in the input mode, and stops timer.

#### ALE (Input)

Negative going edge of the ALE (Address Latch Enable) input latches AD<sub>0</sub>  $\sim$  7, IO/ $\overline{M}$ , and CE signals into the respective latches.

#### **AD**<sup>0</sup> ~ 7 (Input/Output)

Three-state, bi-directional address/data bus. Eight-bit address information on this bus is read into the internal address latch at the negative-going edge of the ALE. Eight bits of data can be read from or written to the chip using this bus, depending on the state of the WRITE or READ input.

#### CE (Input)

When the CE input is high, both read and write operations to the chip are disabled.

#### IO/M (Input)

A high level input to this pin selects the internal I/O functions. A low level selects the memory.

#### RD (Input)

If this pin is low, data from either the memory or ports is read onto the AD<sub>0</sub>  $\sim$  7 lines, depending on the state of the IO/M line.

#### WR (Input)

If this pin is low, data on lines  $AD_0 \sim \tau$  is written into either the memory or into the selected port, depending on the state of the IO/ $\overline{M}$  line.

#### **PA**0 ~ 7, **PB**0 ~ 7 (Input/Output)

General-purpose I/O pins. Input/output directions can be determined by programming the command/status (C/S) register.

#### PC0 ~ 5 (Input/Output)

Three pins are usable either as general-purpose I/O pins or control pins for the PA and PB ports. When used as control pins, they are assigned to the following functions:

- PC0 : A INTR (port A interrupt)
- PC1 : <u>A BF (port A full)</u>

PC2: A STB (port A strobe)

PC3 : B INTR (port B interrupt)

- PC4 : B BF (port B buffer full)
- PC5 : B STB (port B strobe)

TIMER IN (Input)

Input to the counter/timer

#### TIMER OUT (Output)

Timer output. When the present count is reached during timer operation, this pin provides a square-wave or pulse output, depending on the programmed control status.

## Function

81C55 has 3 functions:

- 2K bit, static RAM (256 words × 8 bits)
- Two 8-bit I/O ports (PA and PB) and a 6-bit I/O port (PC)
- 14-bit timer counter

The internal register is shown in the figure below, and the I/O addresses are described in the table following.

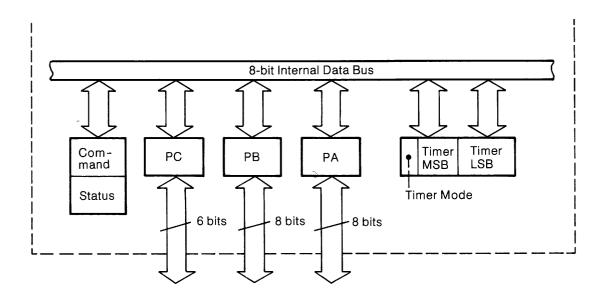

Figure C-7. Internal Register of 81C55

			I/O Ac	dress	6			Colocting Desister			
A7	A6	A5	A4	A3	A2	A1	A0	Selecting Register			
Х	Х	Х	Х	Х	0	0	0	Internal command/status register			
Х	Х	Х	Х	Х	0	0	1	Universal I/O port A (PA)			
Х	Х	Х	Х	Х	0	1	0	Universal I/O port B (PB)			
Х	Х	х	Х	Х	0	1	1	I/O port C (PC)			
Х	Х	Х	Х	X	1	0	0	Timer count lower position 8 bits (LSB)			
Х	х	х	Х	X	1	0	1	Timer count upper position 6 bits and timer mode 2 bits (MSB)			

X: Don't care.

Table C-4. I/O Address of 81C55

#### (1) Programming the Command/Status (C/S) Register

The contents of the command register can be written during an I/O cycle by addressing it with an I/O address of xxxxx000. Bit assignments for the register are shown below:

#### Figure C-8. Programming the Command/Status Register

Pin	ALT1	ALT2	ALT3	ALT4
PC <sub>0</sub>	Input port	Output port	A INTR	A INTR
PC <sub>1</sub>	Input port	Output port	A BF	A BF
PC <sub>2</sub>	Input port	Output port	A STB	A STB
PC <sub>3</sub>	Input port	Output port	Output port	B INTR
PC4	Input port	Output port	Output port	B BF
PC₅	Input port	Output port	Output port	B STB

#### (2) Reading the C/S Register

The I/O and timer status can be accessed by reading the contents of the Status register located at I/O address xxxxx000. The status word format is shown below:

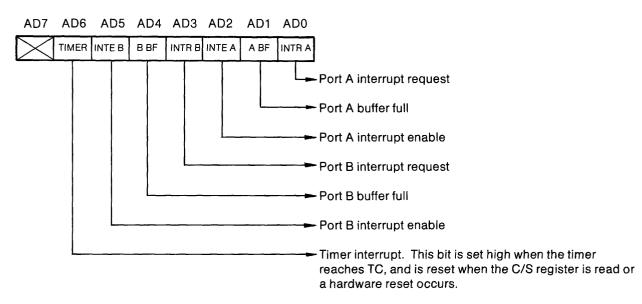

Figure C-9. Reading the C/S Register

#### (3) PA and PB Registers

These registers may be used as either input or output ports depending on the programmed contents of the C/S register. They may also be used either in the basic mode or in the strobe mode.

I/O address of the PA register : xxxxx001 I/O address of the PB register : xxxxx010

#### (4) PC Register

The PC register may be used as an input port, output port or control register depending on the programmed contents of the C/S register. The I/O address of the PC register is xxxxx011.

#### (5) Timer

The timer is a 14-bit counter which counts TIMER IN pulses.

The low order byte of the timer register has an I/O address of xxxxx100, and the high order byte of the register has an I/O address of xxxxx101.

The count length register (CLR) may be preset with two bytes of data. Bits 0 through 13 are assigned to the count length: bits 14 and 15 specify the timer output mode. A read operation of the CLR reads the contents of the counter and the pertinent output mode. The initial value range which can initially be loaded into the counter is 2 through 3FFF hex. Bit assignments to the timer counter and possible output modes are shown in the following.

M2 N	41   T13	T12	T11	T10	Т9	T8
------	----------	-----	-----	-----	----	----

Output mode High order 6 bits of count length

T7	T6	T5	T4	Т3	T2	T1	Т0

Low order byte of count length

Figure C-10. Bit Assignments to the Timer Counter

#### M<sub>2</sub> M<sub>1</sub>

- 0 0 Outputs a low-level signal in the latter half (Note 1) of a count period.
- 0 1 Outputs a low-level signal in the latter half of a count period, automatically loads the programmed count length, and restarts counting when the TC value is reached.
- 1 0 Outputs a pulse when the TC value is reached.
- 1 1 Outputs a pulse each time the preset TC value is reached, automatically loads the programmed count length, and restarts from the beginning.
- **Note 1 :** When counting an asymmetrical value such as (9), a high level is output during the first period of five, and a low level is output during the second period of four.
- **Note 2 :** If an internal counter of the 81C55 receives a reset signal, count operation stops but the counter is not set to a specific initial value or output mode. When restarting count operation after reset, the START command must be executed again through the C/S register.

#### (6) Standby Mode

The 81C55 is placed in standby mode when the high level at  $\overline{CE}$  input is latched during the negative-going edge of ALE. All input ports and the timer input should be pulled up or down to either Vcc or GND potential.

When using battery back-up, all ports should be set low or in input port mode. The timer output should be set low. Otherwise, a buffer should be added to the timer output and the battery should be connected to the power supply pins of the buffer.

By setting the reset input to a high level, the standby mode can be selected. In this case, the command register is reset, so the ports automatically set to the input mode and the timer stops.

## C-3. 6402

### **General Description**

The 6402 is a C-MOS LSI subsystem for interfacing the CPU to an asynchronous serial data channel. The receiver converts serial start, data, parity and stop bits to parallel data verifying proper code transmission, parity and stop bits. The transmitter converts parallel data into serial form and automatically, adds start, parity and stop bits. The data word length can be 5, 6, 7 or 8 bits. Parity may be odd or even. Parity checking and generation can be inhibited. The stop bits may be one or two or one and one-half when transmitting 5 bits code.

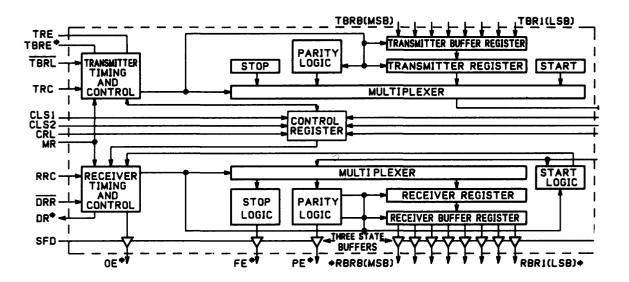

Figure C-11. Functional Block Diagram

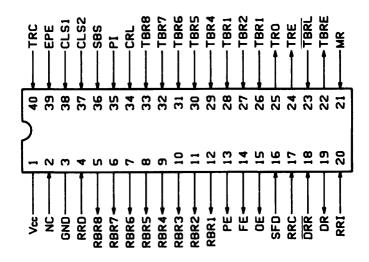

Figure C-12. Pin Configuration of 6402

## **Functional Pin Description**

#### RRD (Input)

A high level on RECEIVER REGISTER DISABLE forces the receiver holding outputs RBR1-RBR8 to a high impedance state.

#### RBR1-8 (Output)

The contents of the RECEIVER BUFFER REGISTER appear on these three-state outputs. Word formats less than 8 characters are right justified to RBR1.

#### PE (Output)

A high level on PARITY ERROR indicates received parity does not match parity programmed by control bits. When parity is inhibited, this output is low.

#### FE (Output)

A high level on FRAMING ERROR indicates the first stop bit was invalid.

#### OE (Output)

A high level on OVERRUN ERROR indicates the data received flag was not cleared before the last character was transferred to the received buffer register.

#### SFD (Input)

A high level on STATUS FLAGS DISABLE forces the outputs PE, FE, OE, DR, TBRE to a high impedance state.

#### RRC (Input)

The RECEIVER REGISTER CLOCK is 16X the receiver data rate.

#### DRR (Input)

A low level on DATA RECEIVED RESET clears the data received output DR to a low level.

#### **DR** (Output)

EA high level on DATA RECEIVED indicates a character has been received and transferred to the receiver buffer register.

#### RRI (Input)

Serial data on RECEIVER REGISTER INPUT is clocked into the receiver register.

#### MR (Input)

A high level on MASTER RESET clears PE, FE, OE, and DR to a low level and sets the transmitter output to a high level after 18 clock cycles. MR does not clear the receiver buffer register. This input must be pulsed at least once after power up.

#### **TBRE** (Output)

A high level on TRANSMITTER BUFFER REGISTER EMPTY indicates the transmitter buffer register has transferred its data to the transmitter register and is ready for new data.

#### TBRL (Input)

A low level on TRANSMITTER BUFFER REGISTER LOAD transfers data from inputs TBRE1-8 into the transmitter buffer register. A low to high transition on TBRL indicates data transfer to the transmitter register is busy, transfer is automatically delayed so that the two characters are transmitted end to end.

#### TRE (Output)

A high level on TRANSMITTER REGISTER EMPTY indicates completed transmission of a character including stop bits.

#### TRO (Output)

Character data, start and stop bits appear serially at the TRANSMTTER REGISTER OUTPUT.

#### TBR1-8 (Input)

Character data is loaded into the TRANSMITTER BUFFER REGISTER via inputs TBR1-8. For character formats less than 8 bits the TBR8, 7 and 6 inputs are ignored corresponding to the programmed word length.

#### CRL (Input)

A high level on CONTROL REGISTER LOAD loads the control register.

#### PI (Input)

A high level on PARITY INHIBIT inhibits parity generation. Parity checking forces PE output low.

#### SBS (Input)

A high level on STOP BIT SELECT selects 1.5 stop bits for 5 bits character format and 2 stop bits for the other lengths.

#### CLS1, CLS2 (Input)

These inputs program the CHARACTER LENGTH SELECTED (CLS1 low, CLS2 low: 5 bits) (CLS1 high, CLS2 low: 6 bits) (CLS1 low, CLS2 high: 7 bits) (CLS1 high, CLS2 high: 8 bits).

#### EPE (Input)

When PI is low, a high level on EVEN PARITY ENABLE generates and checks even parity. A low level selects odd parity.

#### TRC (Input)

The TRANSMITTER CLOCK is 16X the transmit data rate.

CONTROL WORD

Table C-6. Control Word Format

### Function

#### **Receiver Operation**

Data is received in serial form at the RRI. When no data is being received, RRI must remain high. The data is clocked through the RRC. The clock rate is 16 times the data rate.

- [A] A low level on DRR clears the DR line.
- [B] During the first stop bit data is transferred from the receiver register to the RBR. If the word is less than 8 bits, the unused most significant bits will be a low level. The output character is right justified to the least significant bit RBR1. A high level on OE indicates overruns. An overrun occurs when DR has not been cleared before the present character was transferred to the RBR.
- [C] One clock cycle later, DR is reset to a high level and FE is evaluated. A high level on FE indicates an invalid stop bit was received, a framing error. A high level on PE indicates a parity error.

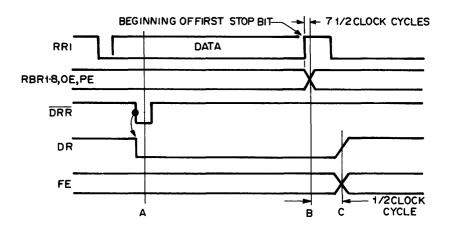

Figure C-13. Receiver Timing

#### **Transmitter Operation**

The transmitter section accepts parallel data, formats it and transmits it in serial form on the TRO terminal.

- [A] Data is loaded into the transmitter buffer register from the inputs TBR1-8 by a logic low on the TBRL input. Valid data must be present at least t-SET prior to and t-HOLD following the rising edge of TBRL. If word less than 8 bits are used, only the least significant bits are used. The character is right justified into the least significant bit, TR1.
- [B] The rising edge of TBRL clears TBRE. 0 to 1 clock cycles later, data is transferred to the transmitter register, TRE is cleared, TBRE is set high, and serial data transmission is started. Output data is clocked by TRC. The clock rate is 16 times the data rate.
- [C] A second pulse on TBRL loads data into the transmitter buffer register. Data transfer to the transmitter register is delayed until transmission of the current character is complete.
- [D] Data is automatically transferred to the transmitter register and transmission of that character begins one clock cycle later.

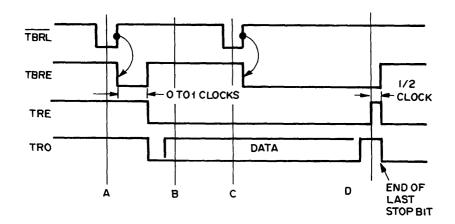

Figure C-14. Transmitter Operation

#### **Start Bit Detection**

The receiver uses a 16X clock for timing. The start bit could have occurred as much as one clock cycle before it was detected, as indicated by the shaded portion. The center of the start bit is defined as clock count 7-1/2. If the receiver clock is a symmetrical square wave, the center of the start bit will be located within  $\pm 1/2$  check cycle,  $\pm 1/32$  bit or 3.125% giving a receiver margin of 46.875%. The receiver begins searching for the next start bit at the center of the first stop bit.

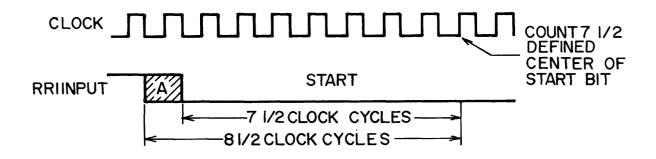

Figure C-15. Start Bit Detection Timing

# C-4. Basic Construction of LCD

Liquid crystal is a substance midway between a liquid and a solid, although its appearance is much like a liquid. From an electrical and optical stand point, it possesses the properties of a crystal. Items which use this substance are called liquid-crystal display elements. The LCD used in the Tandy 102 is a TN (Twisted Nematic) type of liquid crystal. Its basic construction is shown in Figure C-16.

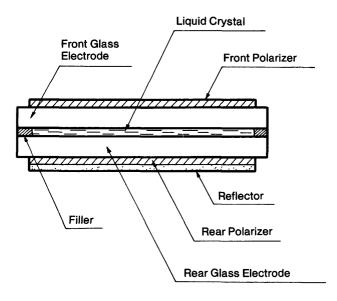

Figure C-16. Construction of LCD Panel

The LCD operates as an "electric shutter" that controls the passage of light. If voltage is applied, the transmission of light is blocked, otherwise, light is allowed to pass so that letters and numbers can be displayed.

Figure C-17 demonstrates how the LCD operates:

- The liquid-crystal display element is sandwiched between the two polarization plates. The polarized axes of the upper and lower plates are placed at right angles to each other to use the optical "twisting" of light.
- As shown in Figure C-17 (a), if voltage is not applied, the liquid-crystal molecules between the upper and lower plates twist 90° to distribute light. This results in a 90° optical movement and the transmission of light.
- In Figure C-17 (b), however, voltage is applied and the liquid appears frosted in current-carrying areas, thus blocking light transmission.

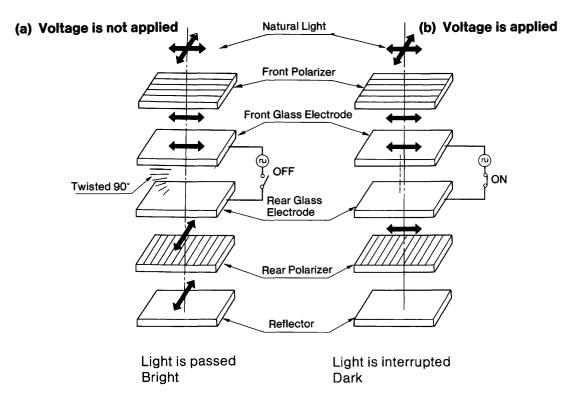

Figure C-17. Operation Theory of LCD Panel
